Costs of poor OSH – Towards an EU-28 estimate

Expert meeting on the costs of accidents and illhealth at work

EU-OSHA Report – review of methodologies Bilbao, 19 June 2014

Xabier Irastorza
Project Manager, PRU

European Agency

for Safety and Health

Background: diversity of estimates

- ILO: 4% of the world's annual GDP is lost as a consequence of occupational diseases and accidents = € 490 billion for EU27
- EU-OSHA (1997): range from 2.6% to 3.8% of GDP –variety of cost factors included.

Country	Estimate % share GDP	Year
Netherlands	3.0	2004
Finland	2.0	2000
Spain	1.7	2004
United Kingdom	1.0	2010
Slovenia	3.5	2000
Australia	4.8	2009
New Zealand	3.4	2006
Germany	3.1	2011
Austria	2.7	2008

Estimating the costs of accidents and ill-health at work – a review of methodologies

Aim:

- Provide policy makers with relevant information on the economic impact of poor or non-OSH at macro level.
- Highlight contribution of OSH to improving productivity and competitiveness.
- Raise awareness about the costs of non-OSH among policy makers outside the field of OSH.

Content:

- Report policy-oriented review of methodologies that quantify the economic impact of work-related accidents and ill-health
- Executive summary for policy makers: translated into eight languages.
- Expert meeting: consolidate report and steps ahead

Estimating the costs of accidents and ill-health at work – a review of methodologies

- Contractor: TNO and Matrix / published on 12 May 2014
- Selection criteria of models for full review (two of three):
 - cover several industries /one of the main industries when it comes to OSH (e.g. construction);
 - not focused on a specific type of injury/illness;
 - relating to one of the EU Member States.

Estimation of the cost of accidents and ill-health at work

<u>Two</u> key steps required to provide a quantitative estimate of the cost of occupational injuries and illnesses:

- 1. the identification of the number of cases and
- 2. the application of monetary values to the identified cases.

1. Identification of the number of cases

- Most studies drew on existing literature, surveys and statistics – typically labour force surveys, compensation statistics:
 - In some studies, <u>survey data</u> was directly used to establish the number of cases.
 - 'Population Attributable Risk' method.
 - Incidence vs. prevalence:
 - Incidence: estimating new cases in a given year (and then calculating all future costs for those cases);
 - Prevalence: estimating all cases in a given year.
- Significant potential for underestimation
 - Long-latency disease cause may be difficult to establish.
 - Small-scale incidents/cases that do not result in a long absence from work (or may not be reported at all).
 - Further research on narrowing down the extent of underestimation and statistically accounting for it is recommended.

2. Application of monetary values – Estimation of costs

Costs were categorized into five main types:

- Productivity costs: costs related to loss of output or production.
- Health care costs: medical costs, including both direct (e.g. pharmaceuticals) or indirect (e.g. caregiver time).
- Quality of life losses: monetary valuation of the loss of quality of life, such as physical pain and suffering.
- Administration costs: costs of administration, for example, applying for social security payments or reporting on a workplace accident.
- Insurance costs: costs regarding insurance, such as compensation payments and insurance premiums.

2. Application of monetary values – Estimation of costs

Costs to four stakeholders:

- Workers and family: the affected individual and close family or friends who are impacted by the injury or illness.
- Employers: the company or organisation that the affected individual works for.
- Government: the relevant public authority regarding, for example, social security payments.
- Society: all stakeholders the effect on society is the overall impact of an injury or illness, excluding transfers between stakeholders (which cancel out).

Conclusions

- The best approach for an EU-wide calculation of costs would probably be an aggregation of national studies, with relevant structural differences highlighted.
- Use of standardised method, e.g. following HSE or Safe Work Australia.
- Include all stakeholders and as many cost categories as possible –quality of life often not included
- Underreporting try and assess it in sensitivity analysis (expert opinion)

Next steps

- Today- Expert meeting to discuss overview report and possible way forward for an EU-28 estimate.
- September 2014 Workshop on cost and benefits of OSH with Dutch FOP – main focus on the business level.
- 2015-2016 OSH overview project and costs and benefits of OSH

Aims of the expert meeting

- Discuss report
- Estimating the costs of accidents and ill-health at EU-28 level
 - Factors for EU-OSHA to take into account: limitations, challenges, opportunities,...
- Methodological approach
- Next

Thank you!
